

IEA Weyburn CO₂ Monitoring and Storage Project Long-term Assessment of Fate of CO₂: Treatment of Abandoned Wells

Mike Stenhouse, Wei Zhou, Monitor Scientific LLC
Rick Chalaturnyk, Francisco Moreno, University of Alberta
Waleed Jazrawi, Project Director, PTRC

**2nd Annual Conference on Carbon Sequestration,
Hilton Alexandria, May 5-8, 2003**

Outline of Talk

- **Introduction to Weyburn EOR**
- **Assessment framework (methodology)**
- **Abandoned wells - issues and treatment**
- **Integration of results (planned!)**

Weyburn Unit

(Slide courtesy of EnCana)

Field Size: 70 sq. miles

CO₂ injection started Sept. '00
CO₂ injected: 49 bcf (Dec. '02)

Weyburn EOR - Introduction

Monitor Scientific

Long-Term Assessment: Context

- **PERFORMANCE MEASURES**

- *Environmental-global*: whether any leakage of CO₂ compromises GHG reduction objectives
- *Environmental-local*: whether any leakage of CO₂ represents an environmental risk to the local population (CO₂ concentration in air, water quality, toxic metal release)

- **TIMESCALE**

- Governs what processes should be considered
- Hundreds to thousands of years (modeling up to 5,000 years)

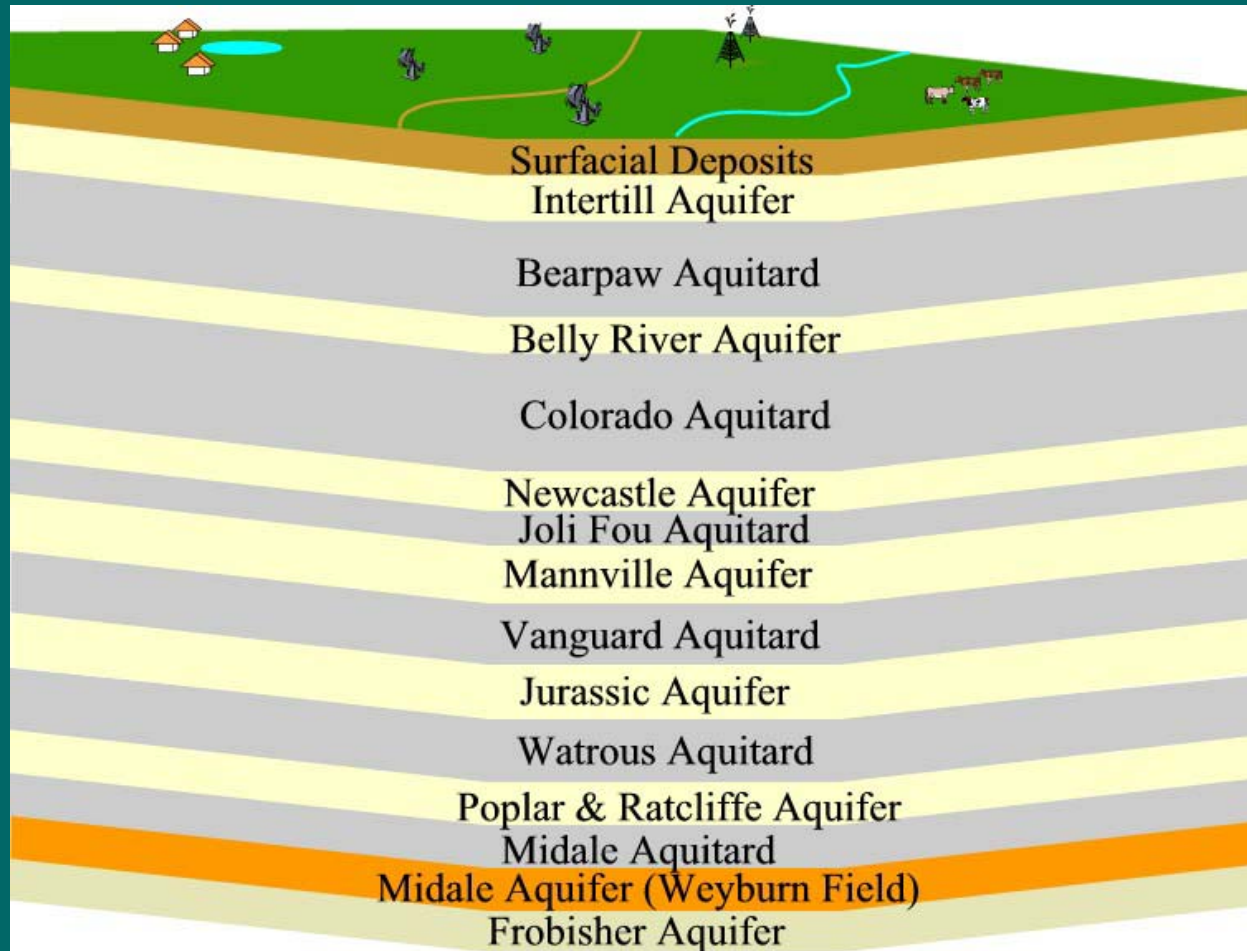

Long-Term Assessment Framework

- *Systems Analysis*
- **Define Weyburn CO₂ ‘System’**
 - storage field + surrounding geosphere + surface/near-surface environment, including atmosphere
- **Identify possible ways in which the System can evolve**
 - Base Scenario
 - Alternative Scenarios

Vertical Extent of Weyburn System

Assessment framework

Monitor Scientific

Map of Wellbores (Phase 1A)

Total of ~180 wellbores

Weyburn - Base Scenario

- Defined as the “expected evolution of the Weyburn CO₂ storage system”
 - CO₂ migration pathways will be a combination of *natural* and *man-made* pathways
 - Wellbore casing seals will be assumed not to leak at time zero
 - CO₂ - rock - water interactions (long-term geochemical modeling)

Assessment framework

Monitor Scientific

Possible Leakage Paths for CO₂

Probabilistic Treatment of CO₂ Leakage via Abandoned Wells

- *Not all wells are, or will be, equal*
- **Need to address heterogeneities in**
 - **Transport parameters**
 - **Reservoir rock**
 - **Wellbore and annular seals (evolution with time)**
 - **Fluid distribution in reservoir**
 - **Hydraulic connection between wellbore and surrounding formations (metal casing corrosion)**

“Unit Cell” Representation of Abandoned Well

Approach to Abandoned Wells

- Detailed study being carried out by University of Alberta (UofA), using ‘real’ data to:
 - examine conditions of wellbores, both pre-CO₂ injection and post-CO₂ injection (EOR) phases
 - predict impact of geomechanical and geochemical effects on transport properties and, hence, leakage of CO₂
- UofA results will then be used by Monitor Scientific (MSCI) as input to long-term assessment

Wellbore Leakage: Information /Data Input

- Well file information (well file database)
- Digital records (logs, production, injection)
- Simulation results (reservoir)
- Geologic 3-D Model
- Analytical Models (*e.g.* geochemical, geomechanical)
- Numerical Models (*e.g.* borehole stability)
- Laboratory Experiments

Vertical Well Layout - Class 1A

141/08-06-006-13W2/00

Spud Date 5/28/1986

Surface Casing Information

Casing Size: 311
 Drilled Hole Size: 219
 Surface Cement: 0:1:0 "G" + 3% D65

Production Casing Information

Drilled Hole Size: 200
 Casing Size: 140
 Production Cement: 2:1:1PZ3 "G" + 0.3% D65+ 2%
 D33 = RFC + 0.9 D127+ 0.1%
 of Gastress

Perforation Information

General Information

Vertical Well Layout

Abandoned wells - issues

Monitor Scientific

Wellbore Annulus Seal Heterogeneity

Wrong density

Poor mud/filter-cake removal

Premature gelation

Excessive fluid loss

Highly permeable slurry

High shrinkage

Cement failure under stress

Poor interfacial bonding

Abandoned wells - issues

Monitor Scientific

Assessment of Wellbore Leakage

Wellbore history

Abandoned Wells: Long-Term Evolution

Chemical/Geochemical Changes

- *Degradation of cement* (casing seals, annular seals)
 - Carbonation, attack by sulphate, chloride
 - Changes in porosity, permeability will affect transport properties of seals
- *Corrosion of metal casing*
 - Ultimately, localized casing failure will allow hydraulic connection with surrounding formations

Interaction of Supercritical CO₂ with Cement

- Overall effect comprises accelerated carbonation, depth penetration, and even greater porosity reduction than under 'natural' conditions
- Mechanical effects?
 - possible brittle nature of carbonated cement phases?
 - potential for cracking?

Process Modelling: CO₂ Flow in Wells

Conceptual model

*Results format
[Flux = $f(P)$]*

Integration of results

Assessment of Abandoned Wells:

Output – Combined Wells

Hypothetical output

- “Real” field data (well files, production data, etc.), combined with analytical or numerical simulations, used to quantify the likelihood of “leakage” from individual wells.
- Focus attention on higher risk areas for post-CO₂ injection phase assessment

Phase 1A Results: Input to Long-Term Assessment

- Extrapolation of detailed (Phase 1A) results to entire assessment area
 - Assume similar statistics for Phase 1A predictions apply to rest of field (assumption can be tested)
- Use predicted well flux rates as distributed *sinks* with respect to CO₂ migration modeling in the geosphere

Integration of results

Monitor Scientific

Acknowledgements

- *The long-term assessment relies on information/data being provided by almost all Research Providers involved in the IEA CO₂ Monitoring and Storage Project*
